

Apparatus having means for realigning a stack of record carriers to be printed

The invention relates to an apparatus as defined in the opening part of claim 1.

Such an apparatus has been put on the market by the applicant under the type
5 designation PPF271 and is consequently known. The known apparatus is a facsimile
apparatus into which a stack of record carriers to be printed, i.e. blank sheets, can be loaded,
namely into holder means of the known apparatus, apparatus-mounted stop means ensuring
that when a stack is loaded into the known apparatus the stack of record carriers to be printed
also has a perfect stack shape, which means that all the record carriers to be printed of the
10 stack are exactly aligned. After a stack of record carriers to be printed has been loaded into
the known apparatus the known apparatus can carry out successive printing operations, for
example during the reception of a facsimile message. As a result of the successively carried
out printing operations the situation arises that in the known apparatus several record carriers
to be printed have been withdrawn from the stack and have been moved away from the
15 holder means towards the withdrawal means. Thus, these record carriers to be printed occupy
a so-called advanced feed position. When in this operating condition of the known apparatus
a replenishment of record carriers to be printed is required, i.e. when an additional stack of
record carriers to be printed should be loaded into the apparatus, the load-exerting means in
the apparatus are moved out of their load-exerting position into their no-load position with
20 the aid of actuating means, so as to guarantee that subsequently an additional stack of record
carriers to be printed can be inserted into the holder means without being influenced by the
load-exerting means. When in the known apparatus the load-exerting means in the apparatus
are moved out of their load-exerting position into their no-load position any record carriers to
be printed which are situated already very close to the withdrawal means remain in their so-
25 called advanced-feed position, as a result of which a stack of record carriers to be printed,
which has subsequently been inserted into the holder means, lies on top of said record
carriers which have already been advanced, which during a subsequent withdrawal by the
withdrawal means of a record carrier to be printed may result in not just a single record
carrier to be printed but, unfortunately, a plurality of such record carriers to be printed being

09761234.011501

withdrawn from the stack and thus being removed from the holder means with the aid of the withdrawal means, which gives rise to a malfunction.

It is an object of the invention to preclude the afore-mentioned problems and to provide an improved apparatus of the type defined in the opening part of claim 1, in which a withdrawal of a plurality of record carriers to be printed from the holder means caused by advanced record carriers is not possible.

According to the invention an apparatus as defined in the opening part of claim 1, in addition, has the characteristic features as defined in the characterizing part of claim 1.

In an apparatus in accordance with the invention it is achieved in a simple manner that during a movement of the load-exerting means with the aid of the actuating means any record carriers to be printed which have already been moved partly from the stack in the holder means towards the withdrawal means are returned onto the stack in the holder means so as to restore a correct stack shape, which results in a correct stacking with accurately aligned record carriers to be printed after an additional stack of record carriers to be printed has been loaded into the holder means, as a result of which the stack does not contain any record carriers which have been advanced towards the withdrawal means in an undesirable manner. Thus, it is achieved that during a subsequently withdrawal process an incorrect, i.e. a multiple, withdrawal of record carriers to be printed, i.e. a multiple removal of record carriers to be printed from the holder means, is precluded. Consequently, a malfunction caused by a multiple removal of record carriers to be printed is also precluded.

In an apparatus in accordance with the invention the realignment means may be driven or actuated in different ways. For example, a construction may be chosen in which the realignment means are movable with the aid of the actuating means. It has proved to be very advantageous when an apparatus in accordance with the invention, in addition, has the characteristic features as defined in claim 2. The direct cooperation of the realignment means with the load-exerting means guarantees a high reliability. This solution has also proved to be advantageous in view of a simple construction.

In an apparatus in accordance with the invention, in which the realignment means are movable from their rest position into their realignment position with the aid of the load-exerting means, it has further proved to be advantageous when, in addition, the characteristic features as defined in claim 3 are provided. This has proved to be advantageous

09761234.01.1601

in view of a particularly simple construction and in view of a very simple actuation of the realignment means.

In an apparatus in accordance with the invention it has proved to be particularly advantageous when, in addition, the characteristic features as defined in claim 4 are provided. Thus, it is achieved in a simple manner that even advanced record carriers, which have already, though only slightly, entered into engagement with the withdrawal means for the withdrawal of each time one record carrier, are returned onto the stack of record carriers to be printed because this is readily possible with the aid of the realignment means without any problems and without being hindered by the withdrawal means after the withdrawal means have been rendered inoperative.

The above-mentioned as well as further aspects of the invention will become apparent from the embodiment described hereinafter by way of example and will be elucidated with reference to this example.

The invention will now be described in more detail with reference to the drawings, which show an embodiment given by way of example but to which the invention is not limited.

Fig. 1 is an oblique plan view of an apparatus in accordance with the invention in accordance with an embodiment of the invention, a scanning device of the apparatus being removed from the apparatus and, as a consequence, not being shown in Fig. 1.

Fig. 2 is a partly diagrammatical cross-sectional view which shows a relevant part of the apparatus shown in Fig. 1, which part of the apparatus includes load-exerting means for exerting a load on a stack of record carriers to be printed, actuating means for the load-exerting means, and realignment means for re-aligning record carriers to be printed.

Fig. 3 is a cross-sectional view which shows a part of the apparatus of Figs. 1 and 2 to an enlarged scale as compared with Fig. 2, which part includes the load-exerting means, the actuating means and the realignment means, the load-exerting means being shown in their load-exerting position and the realignment means in their rest position.

Fig. 4, in the same way as Fig. 3, shows the part of the apparatus of Figs. 1 and 2, the load-exerting means being shown in their no-load position and the realignment means in their realignment position.

Fig. 1 shows an apparatus 1 in accordance with an embodiment of the invention. In the present case, the apparatus 1 is a facsimile apparatus, hereinafter briefly referred to as the apparatus 1.

A first stack 2 of record carriers to be printed can be loaded into the apparatus 1 in a direction indicated by an arrow 3, which stack 2 is shown in dash-dot lines in Figs. 1 and 2. In its loaded condition the stack 2 lies on a supporting plate 4 of the apparatus 1.

Moreover, a second stack 5 of record carriers to be scanned can be loaded into the apparatus 1 in a direction indicated by an arrow 6. The second stack 5 is also shown in dash-dot lines. In its loaded condition the stack 5 lies against a guide plate 7 of the apparatus 1, which guide

plate 7 is connected to additional actuating means with the aid of which load means for exerting a load on the first stack 2 of record carriers to be printed in the leading-edge areas of these record carriers can be reset, as will be described in more detail hereinafter. The

currently uppermost record carrier to be printed can be withdrawn from the stack 2 of record carriers to be printed and can subsequently be fed to a printing roller and thereupon out of the apparatus 1 in a direction indicated by an arrow 8, as is shown in dash-dot lines in Fig. 1.

Likewise, the currently uppermost record carrier to be scanned can be withdrawn from the second stack 5 of record carriers to be scanned and can be fed to a scanning device of the apparatus 1, which scanning device is not shown in Fig. 1 and by means of which it is possible to scan the graphic content of the respective record carrier to be scanned, after which the record carrier just scanned can be fed out of the apparatus 1 in the direction indicated by an arrow 9, as is also shown in dash-dot lines in Fig. 1.

The other parts of the apparatus 1 which are shown in Fig. 1, such as the housing, a telephone keypad, an alphanumeric keypad, a display device and the like, will not be described in any further detail.

The apparatus 1 is constructed to print a record carrier to be printed, which can be fed out of the apparatus 1 in the direction indicated by the arrow 8. The apparatus 1 is further constructed to scan a record carrier 11 to be scanned, which can be fed out of the apparatus 1 in the direction indicated by the arrow 9. This construction will be described in more detail with reference to Fig. 2.

The apparatus 1 includes a printing device 12 having a print head 13. The print head 13 is a thermal print head which is substantially strip-shaped and by means of which it is possible to print in a point-by-point fashion. This printing is effected on a record carrier 10 to be printed, i.e. a blank sheet. The record carrier 10 to be printed can be driven in steps with the aid of a printing roller 15 which is drivable in a direction indicated by an arrow 14 (i.e.

clockwise). The printing roller 15 cooperates with the print head 13. The printing roller 15 is mounted in the apparatus 1 so as to be rotatable, but apart from that it is stationary. The printing device 12 is held against the printing roller 9 with the aid of spring means, not shown, the print head 13 thus being urged against the printing roller 15 under spring load.

5 The printing device 12 including its print head 13 is pivotable about an axis 16 and is movable away from the printing roller 15 in a direction indicated by an arrow 17. The movement of the printing device 12 away from the printing roller 15 is effected with the aid of an actuating device which is not shown in Fig. 1 and which can be driven by means of the printing roller 15.

10 In the apparatus 1 a thermal-transfer printing process can be performed by means of the print head 13. In this thermal-transfer printing process a thermal-transfer foil is heated in a point-by-point fashion with the aid of the print head 13, as a result of which a wax-like dye carried by the thermal transfer foil is transferred to the record carrier 10 to be printed. Said thermal transfer foil is wound onto a first reel 18, the first reel 18 with the
15 supply of thermal transfer foil being carried by a supply mandrel 19. From the first reel 18 the thermal transfer foil is led to a second reel 21 along a feed path 20 shown as a dash-dot line, which second reel is carried by a take-up mandrel 22. The take-up mandrel 22 can be driven by the printing roller 15 in a direction indicated by an arrow 24 via a transmission gear 23, which is shown partly in Fig. 2.

20 In order to print a record carrier 10 to be printed such a record carrier 10 to be printed should be withdrawn from a blank-sheet feeder 25 which contains a stack 2 of such record carriers to be printed, i.e. it should be separated from the stack. For this purpose, the apparatus 1 has a blank-sheet withdrawal roller 26, which is rotationally drivable in a direction indicated by an arrow 27, i.e. clockwise. The currently uppermost record carrier to
25 be printed can be withdrawn from the first stack 2 in the blank-sheet feeder 25 with the aid of the blank-sheet withdrawal roller 26 and be fed into the area between the print head 12 and the printing roller 15. As soon as a record carrier 10 to be printed has reached the printing roller 15, the record carrier 10 to be printed is fed further by means of the printing roller 15, the blank-sheet withdrawal roller 26 then being out of driving engagement, as is already
30 known per se from such apparatus since long. A record carrier 10 to be printed is fed between the blank-sheet feeder 25 and the printing roller 15 along a feed path 28 shown as a dash-dot line in Fig. 2. After the record carrier 10 to be printed has been printed the printed record carrier 10 is fed along a feed path 29, which is likewise shown as a dash-dot line in Fig. 2, and is then fed out of the apparatus 1 in the direction indicated by the arrow 8.

09761234"014501

The apparatus 1 further includes a scanning device 30, by means of which a record carrier 11 to be scanned, i.e. an original document, can be scanned in order to convert the graphic information on the record carrier 11 to be scanned, for example alphanumeric characters, into digital signals. In Fig. 2 the scanning device 30 is shown only diagrammatically.

The scanning device 30 is accommodated in a separate housing. In this way, it is achieved that the scanning device 30 forms a separate unit and can consequently be separated readily and simply from the apparatus 1 so as to be removed from the apparatus 1. In a first mode of operation, in which the scanning device 30 is connected to the apparatus 1, as is illustrated in Fig. 2, as well as in a second mode of operation, in which it is separated from the apparatus 1, as is not shown in the Figures, said scanning device can scan a record carrier 11 to be scanned. In the first mode of operation as shown in Fig. 2, the record carrier 11 to be scanned can be fed past the scanning device 30, which is immobile in the apparatus 1, with the aid of drive means to be described briefly hereinafter. In the second mode of operation the scanning device 30 can be moved by hand over the stationary record carrier 11 to be scanned.

In order to enable scanning of a record carrier 11 to be scanned in the first mode of operation illustrated in Fig. 2, such a record carrier 11 to be scanned must be withdrawn from the second stack of record carriers to be scanned. For this purpose, the apparatus 1 has an original-document withdrawal roller 33, which is rotationally drivable in a direction indicated by an arrow 34 (i.e. clockwise). The original-document withdrawal roller 33 is mounted so as to be rotatable with the aid of a spindle 35. The original-document withdrawal roller 33 can be driven in steps in the direction indicated by the arrow 34, namely with the aid of apparatus-mounted drive means, which are neither shown nor described any further. The original-document withdrawal roller 33 provided as withdrawal means is accommodated in the scanning device 30, which withdrawal roller serves for withdrawing a record carrier 11 to be scanned from the second stack 5 of record carriers to be scanned, the leading edges of the record carriers to be scanned of this stack 5 being situated in the area of the withdrawal means, i.e. in the area of the original-document withdrawal roller 33, as can be seen in Fig. 2.

In order to enable the actual scanning of a record carrier 11 to be scanned after withdrawal of this record carrier 11 to be scanned, the withdrawn record carrier 11 to be scanned should be driven stepwise in the apparatus 1, the withdrawn record carrier 11 to be scanned being fed to an elongate scanning unit 38 during this driving process. The scanning

00761234-011601

unit 38 includes a photoelectrically operating scanning strip 39, which is held in close contact with a record carrier 11 to be scanned, namely in that spring means, not shown, urge the scanning unit 38 towards the record carrier 11 to be scanned.

For driving a withdrawn record carrier 11 to be scanned the apparatus 1 has two original-document drive rollers 40, of which only one original-document drive roller 40 is shown in Fig. 2 and which serve as drive means for driving a withdrawn record carrier 11 to be scanned in the apparatus 1, in order to feed the withdrawn record carrier 11 to be scanned to the scanning unit 38 and move it past the scanning device 30, i.e. past the scanning unit 38. The two original-document drive rollers 40 provided as drive means are also accommodated in the scanning device 30. Like the original-document withdrawal roller 33, the two original-document drive rollers 40 and 41 provided as drive means are also rotatably mounted with the aid of the spindle 35 and are coaxial with the original-document withdrawal roller 33. The two original-document drive rollers 40 consist of a material having a comparatively high coefficient of friction and have a diameter which is slightly greater than the diameter of the original-document withdrawal roller 33. Further details on the construction of the spindle 35 and the original-document withdrawal roller 33 as well as the two original-document drive rollers 40 and 41 can be found in, for example, the patent document US 5,820,121 A.

As regards the drive means for the printing roller 15, the take-up mandrel 22, the blank-sheet withdrawal roller 26 and the original-document drive rollers 40, as well as the original-document withdrawal roller 33, reference is made to the European priority patent application of 23 December 1999 having the application number 99 890 402.3, whose subject matter is incorporated herein by reference.

The following description mainly refers to Figs. 3 and 4. Figs. 3 and 4 do not show the scanning device 30 of the apparatus 1. The first stack 2 is shown only diagrammatically in Fig. 3. The first stack 2 is not shown at all in Fig. 4.

As already stated hereinbefore, the apparatus 1 includes a blank-sheet withdrawal roller 26 by means of which the currently uppermost record carrier to be printed of the first stack 2 can be withdrawn from the blank-sheet feeder 25 and can be fed into the area between the print head 12 and the printing roller 15. The blank-sheet withdrawal roller 26 forms a part of withdrawal means 50, which in addition to the blank-sheet withdrawal roller 26 also include a rubber sheet 51 adapted to cooperate with the circumferential surface of the blank-sheet withdrawal roller 26. To retain the rubber sheet 51 a retaining arm 52 having a plurality of bends has been provided in the area of the blank-sheet feeder 25, which

forms the holder means 25 for holding the first stack 2 of record carriers to be printed, which arm is pivotable about a pivotal axis 53 and retains or carries the rubber sheet in the area of its free end 54. In the area of the free end 54 of the retaining arm 52 a pressure spring, which is shown diagrammatically as a dashed double-headed arrow 55, acts upon the retaining arm 52 and urges the retaining arm 52 and, consequently, the rubber sheet 51 towards the blank-sheet withdrawal roller 26 under spring load. In the operational situation illustrated in Fig. 3 the rubber sheet 51 lies against the circumferential surface of the blank-sheet withdrawal roller 26. In the operational situation shown in Fig. 4 the rubber sheet 51 is lifted off the circumferential surface of the blank-sheet withdrawal roller 26. How the rubber sheet 51 is lifted off the blank-sheet withdrawal roller 26 will be elucidated hereinafter.

The apparatus 1 has load-exerting means 56 in the area of the holder means 25 of the apparatus 1, i.e. in the area of the blank-sheet feeder 25 of the apparatus 1. The load-exerting means 56 are movable between a load-exerting position shown in Fig. 3 and a no-load position shown in Fig. 4. In their load-exerting position the load-exerting means 56 urge the first stack 2 of record carriers to be printed, present in the blank-sheet feeder 25, in its area near the withdrawal means 50 towards the withdrawal means 50 under spring load. In their no-load position the load-exerting means 56 allow the first stack 2 or an additional stack of record carriers to be printed to be inserted into the blank-sheet feeder 25 without being influenced by the load-exerting means 56.

The load-exerting means 56 include a pressure plate 57, which extends substantially over the whole width of a record carrier 10 to be printed. At its side which is remote from the first stack 2 the pressure plate 57 has two stiffening recesses 58, of which only one stiffening recess 58 is visible in the Figures. Two pressure springs 59 (see Fig. 2) act on the pressure plate 57, said springs being indicated only by means of a dashed double-headed arrow in Figs. 3 and 4.

The load-exerting means 56 further include two pivotal arms 60 which are connected to the pressure plate 57 and the stiffening recesses 58 and which project from these elements, only one pivotal arm 60 being visible in Figs. 3 and 4. With the aid of the two pivotal arms 60 the load-exerting means 56 are mounted in the apparatus 1 so as to be pivotable about a pivotal axis 61.

To enable the load-exerting means 56 to be moved from the load-exerting position shown in Fig. 3 into the no-load position shown in Fig. 4 each of the two pivotal arms 60 has a coupling limb 62, which projects laterally from the relevant pivotal arm 60.

09761234 "011601

To move the two coupling limbs 62 and, consequently, the load-exerting means 56 from their load-exerting position into their no-load position the apparatus 1 has actuating means 63. In the present case, the actuating means 63 for moving the load-exerting means 56 are advantageously constructed as guide means for guiding a record carrier 11 to be scanned, which is to be fed to the drive means for driving a record carrier 11 to be scanned, i.e. the two original-document drive rollers 40. The actuating means 63, which also form the guide means, are mounted in the apparatus 1 so as to be pivotable about a pivotal axis 64. The actuating means 63 include the guide plate 7, which is pivotable about the pivotal axis 64. The guide plate 7 has two guide projections 65 and 66 (see Fig. 1), of which only one guide projection 65 is visible in Figs. 3 and 4. The two guide projections 65 and 66 each have a guide surface, the two guide surfaces facing one another and being spaced at a distance from one another, which distance corresponds to the dimension of a record carrier 11 to be scanned in a direction parallel to the pivotal axis 64. In the present case, this distance corresponds to the width of an A4 size sheet of paper.

In addition, the guide plate 7 has two further guide projections 67 and 68 (see Fig. 1) having a shape which essentially corresponds to that of the two guide projections 65 and 66, the distance between the guide surfaces of the two further guide projections 67 and 68 in the present case corresponding to the width of an A5 size sheet of paper.

The distances between the guide projections 65 and 66 and between the further guide projections 67 and 68 may also be different. Moreover, it is possible to use a construction which enables the distances between two associated guide projections to be varied.

The actuating means 63, as already stated, serve for moving the load-exerting means 56. For this purpose, the guide plate 7 is connected to two actuating arms 69, of which only one actuating arm 69 is visible in Figs. 3 and 4. The two actuating arms 69 project from the guide plate 7 towards the withdrawal means 50. Each of the two actuating arms 69 has a cup-shaped actuating projection 70. The two actuating projections 70 have been provided and constructed to cooperate with the two coupling limbs 62 of the load-exerting means 56.

When the actuating means 63 are moved out of their initial position, i.e. pivoted about the pivotal axis 64, in the direction indicated by the arrow 71, the actuating projections 70 engage against the coupling limbs 62 during this pivotal movement, as a result of which the coupling limbs 62 and, consequently, the load-exerting means 56 are moved from their load-exerting position shown in Fig. 3 into their no-load position shown in Fig. 4

09761234-011601

against the action of the pressure springs 59, the actuating means 63 then assuming a position as shown in Fig. 4.

Advantageously, the apparatus 1 has realignment means 75 adjacent the transitional area between the blank-sheet feeder 25 and the withdrawal means 50. In the present case, the realignment means 75 have a two-arm realignment lever 76. The two-arm realignment lever 76 has a realignment arm 77 and a realignment arm 78, forming an actuating portion of the realignment means 75. The two-arm realignment lever 76 is mounted so as to be pivotable about a pivotal axis 79.

The realignment means 75 are movable between a rest position shown in Fig. 3 and a realignment position shown in Fig. 4. When the load-exerting means 56 are moved from their load-exerting position shown in Fig. 3 into their no-load position shown in Fig. 4 with the aid of the actuating means 63, the realignment means 75 are movable from their rest position into their realignment position. The realignment arm 77 of the realignment means 75 effects a realignment of record carriers to be printed which have been moved from the first stack 2 towards the withdrawal means 50. In this way, it is achieved that during a movement of the actuating means 63, in order to allow the introduction of additional record carriers to be printed into the blank-sheet feeder 25, the record carriers to be printed which are already present in the blank-sheet feeder 25 and which have already been fed at least a little way towards the withdrawal means 50 are returned into their initial position in the blank-sheet feeder 25 already before the introduction of additional record carriers to be printed, as a result of which the record carriers to be printed and already present in the blank-sheet feeder form a correctly aligned stack prior to the introduction of additional record carriers to be printed. Thus, it is guaranteed that a correctly aligned stack of record carriers in the blank-sheet feeder 25 is obtained also when additional record carriers to be printed are introduced and after such additional record carriers to be printed have been introduced.

In the apparatus 1 the realignment means 75 are movable with the aid of the load-exerting means 56 from their rest position shown in Fig. 3 into their realignment position shown in Fig. 4. For this purpose, the load-exerting means 56 have an actuating nose 80 which during a movement of the load-exerting means 56 from their load-exerting position into their no-load position enters into operational engagement with the actuating arm 78 of the realignment means 75 and thereby produce a movement, namely a pivotal movement, of the realignment means 75 from their rest position into their realignment position. The opposite movement 75 of the realignment means 75 from their realignment position into the

rest position is obtained under the influence of gravity; however, this movement can alternatively be obtained by means of the next record carrier to be printed that is withdrawn.

The apparatus 1 further includes additional means 81 formed by a further actuating nose 81 which projects laterally from the actuating nose 80 in the area of the

5 actuating nose 80 of the load-exerting means 56. The additional means 81 make it possible to disable the withdrawal means 50 for the withdrawal of each time one record carrier to be printed, when the load-exerting means 56 are moved from their load-exerting position into their no-load position with the aid of the actuating means 63. The withdrawal means 50 are then simply disabled in that during the movement of the load-exerting means 56 from their
10 load-exerting position into their no-load position the additional means 81, i.e. the further actuating nose 81, abuts against the retaining arm 52 for the rubber sheet 51 and subsequently pivots the retaining arm 52 about the pivotal axis 53 away from the blank-sheet withdrawal roller 26, as a result of which the rubber sheet 51 is lifted off the circumferential surface of the blank-sheet withdrawal roller 26, thereby disabling the withdrawal means 50. This
15 guarantees that also record carriers to be printed which are already in operational engagement with the rubber sheet 51 of the withdrawal means 50 are realigned into their initial positions in the blank-sheet feeder 25 with the aid of the realignment means 75.

09761234-011601
